

## ABSTRACT / ZUSAMMENFASSUNG / ABREGE

00128216.9

Method and system involving a client unit (20) and a server unit (10) for executing a service application including a client module (211) and a server module (111). The server unit generates a server request (31) and transmits same to the client unit. The client unit analyzes the server request and starts a client module of the service application at the client unit. A client request (32) is transmitted to the server unit, including an identifier of a server module to be executed at the server unit, for example specified using a URL. At the server unit the server module is executed and a completion indicator (33) after completing the server module is returned to the client unit. The completion indicator may be a response to the URL received from the client module at the client unit and therefore the client module is maintained active until the completion indicator is received. Thus, a synchronization during executing the service application can be maintained.
